

# Inhibitor Gated RNNs – Short Version

## Motivation:

- Quantized Gated RNNs that doesn't use Dot-product and Sigmoid.

## Basic idea:

- Replace Dot-prod with Manhattan distance and Softmax with ReLU

$$QK^T \rightarrow \sum_k |Q_{ik} - K_{jk}|$$
$$\sum_j \text{Softmax}(Z_{ij}) V_{jk} \rightarrow \sum_j (V_{jk} - Z_{ij}^+)^+$$

## Observations:

- Reminiscent of subtractive inhibition in biological neurons.
- Removes variable multiplication and require only *half* precision.
- In the limits the modified gates behaves like the conventional.

## Result:

- Comparable training capacity to the conventional mechanism.
- Reduced precision requirements translate into computational efficiency.
- Substantial gains under FHE by avoiding ciphertext multiplication.

## Potential:

- Natural integer quantization for deployment under resource constraints.
- May enable end-to-end encrypted applications of Gated RNNs.

## Future work:

- Does this architecture generalize to transformers? Answer: Yes.
